

ABSTRACT

The present invention provides a vibration control mount apparatus capable of absorbing an initial pushing-up load based on a shock and capable of promptly damping a residual vibration generated after the shock.

The vibration control mount apparatus 10 includes a case body 11 mounted on a turning frame 3, a mount rubber 14 is mounted on the case body 11. A magnetic viscous fluid 16 of which viscosity is changed by a magnetic field is sealed in a sealing chamber 15 in the case body 11. A movable body 21 supported by the mount rubber 14 has a damper plate 23 which moves while receiving resistance from the magnetic viscous fluid 16 in the sealing chamber 15. Viscosity variable controlling means 32 forms the magnetic field in accordance with vibration acceleration detected by the acceleration detecting means 31 to change the viscosity of the magnetic viscous fluid 16.
